PHARMACOVIGILANCE SYSTEM MASTER FILE (PSMF)

Final Main Body Summary – Workora Internship Task

Prepared by: Atharva Dhage, Pharm D

Objective: Summarise the PV system, QPPV oversight, safety database, signal management, quality systems, SOP index and audit history.

Important: This is an educational sample based on your screenshot. The Workora PSMF Source Pack was not provided, so organization-specific facts are placeholders. Replace/verify them using the actual Source Pack before submitting.

1. Purpose and Scope

The Pharmacovigilance System Master File (PSMF) describes the pharmacovigilance system used by a marketing authorisation holder (MAH) to fulfil its safety-monitoring responsibilities. It supports regulatory oversight, quality management, compliance and inspection readiness.

2. Organisation and System Overview

MAH: [Insert from Source Pack]
PSMF reference: [Insert reference]
Controlled location: [Insert location]
Responsible function: Global Pharmacovigilance / Drug Safety
Scope: Safety monitoring for products and territories within the MAH's defined portfolio.

3. QPPV Oversight and Responsibilities

The Qualified Person Responsible for Pharmacovigilance (QPPV) oversees the establishment and maintenance of the PV system and provides oversight of product safety profiles. Responsibilities include ICSR processing, signal management, risk management, periodic safety reporting, regulatory communications, compliance monitoring and inspection readiness. The QPPV should have access to relevant safety information and authority to support effective PV oversight.

4. Safety Database and Data Management

The safety database supports receipt, validation, duplicate checking, coding, medical assessment, storage, reporting and follow-up of individual case safety reports (ICSRs). Governance should include role-based access, audit trails, validated system controls, backup and recovery, change control, data security, business continuity and reconciliation with relevant data sources. MedDRA coding conventions should be applied consistently where applicable.

5. ICSR Processing Workflow

Case intake and date-stamping → minimum-criteria validation → duplicate search → data entry and medical review → coding → seriousness/expectedness/causality assessment → quality control → regulatory reporting within applicable timelines → follow-up → reconciliation and archival.

6. Signal Management Workflow

Signal detection → validation and prioritisation → assessment and confirmation → evaluation of impact on benefit–risk balance → recommendation of risk-minimisation or regulatory action, if required → documentation and ongoing monitoring. Decisions and rationale should be recorded in controlled records.

7. RMP and Periodic Safety Reporting

The PV system should support preparation and maintenance of Risk Management Plans (RMPs), Periodic Safety Update Reports (PSURs/PBRERs) and other required safety communications according to the product, jurisdiction and applicable regulations. Emerging evidence, safety concerns and the effectiveness of risk-minimisation measures should be assessed and escalated through documented processes.

8. Quality Management System

The QMS should define responsibilities, training, controlled documents, deviations, CAPA, change control, vendor oversight, quality metrics, compliance monitoring, record retention and management review. Deviations should be investigated and addressed proportionately, with effectiveness checks for corrective and preventive actions.

9. SOP Index and Training

The SOP index should record each procedure's title, document number, version, effective date, owner and review status. Relevant procedures may cover adverse-event intake, ICSR processing, expedited reporting, literature screening, signal management, aggregate reporting, RMPs, safety communication, reconciliation, quality management, vendor oversight, training and business continuity. Personnel should complete role-appropriate training and records should be retained.

10. Audit, Inspection and Compliance History

Summarise the audit programme, inspection history, significant findings, compliance monitoring and CAPAs using controlled records. If no audits or inspections occurred during the reporting period, state this only after checking the source records. Do not invent dates, findings, outcomes or compliance percentages.

11. Document Control and Maintenance

Maintain the PSMF under document control. Update it when material changes occur in QPPV details, the PV system, product portfolio, safety database, service providers, procedures or organisational responsibilities. Retain version history and approvals.

12. Conclusion

The PSMF provides a structured overview of PV governance, safety-data processing, signal management, risk management and quality oversight. Before approval, verify all organization-specific fields against the Source Pack and confirm consistency with the current PSMF and source registers.

Source Pack Reconciliation Checklist

- Insert MAH and QPPV details.
- Confirm safety database name, architecture and controls.
- Reconcile signal-management workflow and responsible functions.
- Verify current SOP index and QMS/training records.
- Check audit and inspection history; do not assume there were none.
- Confirm version, approval status and controlled location.
